# String Functions In C++

Last Updated : 31 Oct, 2023

A string is referred to as an array of characters. In C++, a stream/sequence of characters is stored in a char array. C++ includes the `std::string` class that is used to represent strings. It is one of the most fundamental datatypes in C++ and it comes with a huge set of inbuilt functions. In this article, will look at the functions of string computations.

## What is `std::string`?

*The `std::string` is a class in C++ since C++98. This class is the standard representation for a text string. It includes some typical string operations like find, replace, concatenate, compare etc. It is present in `<string>` header file.*

## Declaration and Initialization of String

```
std::string company = "GeeksforGeeks!";
```

## Commonly Used String Functions in C++

The `std::string` class contains functions to provide some common string operations. The below table contains some of the most commonly used functions in C++:

S. No.	Category	Functions and Operators	Functionality
1.	String Length	<a href="#">length() or size()</a>	It will return the length of the string.
2.	Accessing Characters	Indexing (using array[index])	To access individual characters using array indexing.
		<a href="#">at()</a>	Used to access a character at a specified index.
3.	Appending and Concatenating Strings	<i>+ Operator</i>	+ operator is used to concatenate two strings.
		<a href="#">append()</a>	The append() function adds one string to the end of another.
4.	String Comparison	<i>== Operator</i>	You can compare strings using the == operator.
		<a href="#">compare()</a>	The compare() function returns an integer value indicating the comparison result.
5.	Substrings	<a href="#">substr()</a>	Use the substr() function to extract a substring from a string.
6.	Searching	<a href="#">find()</a>	The find() function returns the position of the first occurrence of a substring.
7.	Modifying Strings	<a href="#">replace()</a>	Use the replace() function to modify a part of the string.

S. No.	Category	Functions and Operators	Functionality
		<u><a href="#">insert()</a></u>	The insert() function adds a substring at a specified position.
		<u><a href="#">erase()</a></u>	Use the erase() function to remove a part of the string.
8.	Conversion	<u><a href="#">c_str()</a></u>	To obtain a C-style string from a std::string, you can use the c_str() function.

***Note:** The above functions only works for C++ Style strings (std::string objects) not for C Style strings (array of characters).*

## 1. String Length - length() or size()

We can find the length of the string (number of characters) using either **length()** or **size()** function of the std::string class.

### Syntax

```
string_object.size()
or
string_object.length()
```

### Parameters

- This function does not take any parameter.

### Return Value

- This function returns the number of characters in the string object.

## Example

```
std::string text = "geeksforGeeks";  
int length = text.length();  
//or  
int length = text.size();
```

It will return the length of the string **text** which is 13.

## 2. Accessing Characters - at()

Generally, we can access the character of a string using the **[] array subscript operator** and indexing. But `std::string` also has a function named **at()** which can be used to access the characters of the string.

## Syntax

```
string_object.at(index);
```

## Parameters

- **index:** It represents the position of the character in the string.

## Return Value

- This function returns the character present at the **index**.

## Example

```
std::string str = "GEEKSFORGEEKS";  
std::cout << str.at(3);
```

The `std::cout` will print K on the console as it is the character present at index 3.

## 3. Concatenating Strings - append() or + Operator

We can concatenate string in C++ using two methods:

## 1. + Operator

The + operator is overloaded in the `std::string` class to perform string concatenation.

### Syntax

```
string_object1 + string_object2
```

### Example

```
std::string firstName = "Geeks";  
std::string lastName = "forGeeks";  
std::string fullName = firstName + " " + lastName;
```

+ operator is used to concatenate two strings. The string `fullName` will be "GeeksforGeeks".

## 2. append()

The `append()` function is another member function to concatenate two strings.

### Syntax

```
string_object1.append(string2)
```

### Parameters

- **string2:** This function takes the string to be appended as a parameter. It can be both C or C++ Style string.

### Return Value

- Reference to the final string.

```
std::string base = "Hey! Geeks";  
base.append(" Welcome to GeeksforGeeks!"); // Append a string
```

The `append()` function adds one string to the end of another.

## 4. String Comparison - `compare()` or `==` Operator

Just like the concatenation, we can do the string comparison using two methods:

## 1. == Operator

The equality operator can be used to compare the two strings as it is overloaded for this operation in the `std::string` class.

### Syntax

```
string_object1 == string_object2
```

This will return **true** if both the strings are equal, otherwise returns **false**.

### Example

```
std::string str1 = "apple";  
std::string str2 = "banana";  
if (str1 == str2) {  
    std::cout << "Strings are equal";  
}  
else {  
    std::cout << "Strings are not equal";  
}
```

Here, "Strings are not equal" will be printed as the `==` operator will return **false**.

## 2. compare()

The `compare()` function is a member function of `std::string` class which can be used to compare two strings.

### Syntax

```
str1.compare(str2);
```

### Parameters

- **str2**: It is the string to be compared. It can be both C or C++ style string.

## Return Value

- If the strings are equal, return **zero**.
- If str1 is greater than str2, return value **>0**
- If str2 is greater than str1, return value **<0**

## Example

```
string str1 = "Geeks";  
string str2 = "Geeksfor";  
int result = str1.compare(str2);
```

The result will contain a value less than zero as str2 is greater than str1.

We can also compare the substring of str2 using the compare function():

```
str1.compare(position, length, str2);
```

where,

- **position**: position of the first character substring.
- **length**: length of the substring.
- **str2**: String object to be compared.

## 5. Searching - find()

We can use the **find()** function of the `std::string` class to check whether a given character or a substring is present in the string or a part of string.

### Syntax of find()

```
str1.find(var);
```

### Parameters

- **var**: It can be a C style string, C++ style string, or a character that is to be searched in the string.

### Return Value

- It returns the pointer to the first occurrence of the character or a substring in the string.

### Example

```
std::string text = "C++ Programming";  
int position = text.find("Programming"); // Find the position of a  
substring
```

The position variable will contain 4 which is the start of the first occurrence of the string "Programming" in string text.

## 6. Generate Substring - substr()

We can use the **substr()** function to generate a part of the string as a new string object. It is a member function of the `std::string` class.

### Syntax of substr() in C

```
str1.substr(start, end);
```

### Parameters

- **start**: Starting position of the substring to be generated.
- **end**: Ending of the substring to be generated.

### Return Type

- It returns the newly created string object.

### Example

```
std::string text = "Hello, World!";  
std::string sub = text.substr(7, 5); // Extract "World"
```

In the above example, the **sub** string will contain the "World".

## Modifying Strings

The following function allows us to modify the current string.

### 1. insert()

The `insert()` function not only allows us to add a string but also allows us to add it at the specified position. It is also a member function of the `std::string` class.

### Syntax

```
str1.insert(index, str2);
```

### Parameters

- **str2**: string to be inserted.
- **index**: position of where to insert the new string

### Return Type

- Reference to the `str1`.

### Example

```
std::string text = "I have a cat.";  
text.insert(9, " black"); // Insert " black" at position 9
```

## 2. replace()

The `replace()` function replaces the part of the string with the given other string. Unlike `insert`, the characters in the part where the new string is to be inserted are removed.

### Syntax

```
str1.replace(index, size, str2);
```

### Parameters

- **index**: Index of where to start replacing the new string.
- **size**: length of the part of the string that is to be replaced.
- **str2**: new string that is to be inserted.

### Return Type

- Reference to the `str1`.

## Example

```
std::string text = "I like dogs.";
text.replace(7, 4, "cats"); // Replace "dogs" with "cats"
```

## 3. erase()

The `erase()` function is a member function of `std::string` class that is used to remove a character or a part of the string.

### Syntax

```
str1.erase(start, end);
```

### Parameters

- **start:** Starting position.
- **end:** Ending position.

### Return Type

- Reference to the `str1`.

## Example

```
std::string text = "This is an example.";
text.erase(5, 3); // Erase "is "
```

## Convert std::string to C String - c\_str()

The `c_str()` function is a member function that is used to convert the C++ style string i.e. `std::string` objects to C style string i.e. array of characters.

### Syntax

```
str1.c_str()
```

### Parameters

- This function does not take any parameter.

## Return Value

- Pointer to the equivalent array of characters.

## Example

```
std::string str = "C++";  
const char* cstr = str.c_str();
```

## Example of String Functions in C++

The below code demonstrate the use of the above specified string functions:

**C++**

```
1 // C++ Code to demonstrate various functions available in  
2 // String class  
3  
4 #include <iostream>  
5 #include <string>  
6  
7 using namespace std;  
8  
9 int main()  
10 {  
11     // Creating and initializing strings  
12     string greeting = "Hello, World!";  
13     cout << greeting << endl;  
14     string name;  
15  
16     // Input from the user  
17     cout << "Enter your name: ";  
18     cin >> name;  
19     cout << name << endl;  
20  
21     // String length  
22     int length = greeting.length();  
23     cout << length << endl;  
24  
25     // Accessing characters  
26     char firstChar = greeting[0];  
27     char secondChar = greeting.at(1);  
28     cout << firstChar << " " << secondChar << endl;
```

```
29
30 // Appending and concatenating strings
31 string firstName = "Geek";
32 string lastName = "Geeks";
33 string fullName = firstName + " " + lastName;
34 cout << fullName << endl;
35 string base = "Hello";
36 cout << base << endl;
37 base.append(" World!");
38 cout << base << endl;
39
40 // String comparison
41 string str1 = "apple";
42 string str2 = "banana";
43 if (str1 == str2) {
44     cout << "Strings are equal" << endl;
45 }
46 else {
47     cout << "Strings are not equal" << endl;
48 }
49
50 int result = str1.compare(str2);
51 if (result == 0) {
52     cout << "Strings are equal" << endl;
53 }
54 else if (result < 0) {
55     cout << "str1 comes before str2" << endl;
56 }
57 else {
58     cout << "str1 comes after str2" << endl;
59 }
60
61 // Substrings
62 string text = "Hello, World!";
63 cout << text << endl;
64 string sub = text.substr(7, 5);
65 cout << sub << endl;
66
67 // Searching
68 string searchIn = "C++ Programming";
69 size_t position = searchIn.find("Programming");
70 if (position != string::npos) {
71     cout << "Found at position " << position << endl;
```

```
72     }
73     else {
74         cout << "Not found" << endl;
75     }
76
77     // Modifying strings
78     string modify = "I like dogs.";
79     modify.replace(7, 4, "cats");
80     cout << modify << endl;
81     modify.insert(6, " black");
82     cout << modify << endl;
83     modify.erase(6, 6);
84     cout << modify << endl;
85
86     // Conversion
87     string str = "C++";
88     const char* cstr = str.c_str();
89     cout << cstr << endl;
90
91     return 0;
92 }
```

## Output

```
Hello, World!
Enter your name: Geeks
Geeks
13
H e
Geek Geeks
Hello
Hello World!
Strings are not equal
str1 comes before str2
Hello, World!
World
Found at position 4
I like cats.
I like black cats.
```

```
I like cats.
```

```
C++
```
